2024 Wittgenstein Centre Conference
Vienna, 21-22 November 2024

1. Motivation and hypotheses

- Over the last decades, European countries have experienced an increase in the average age at parenthood (Neels et al., 2017; Billari et al., 2019).
- People often wait to have children until they meet certain conditions (Gustafsson & Kalwij, 2006; Mills et al., 2011; Wood & Neels, 2017; Rotkirch, 2020), such as finding the right partner (Slabá et al., 2024).
- However, because of the age-related fecundity decline (Te Velde et al., 2012; Leridon, 2017), these prerequisites may vary in importance depending on a woman's age.

1. Motivation and hypotheses

We expect to find:

Older women to approach these requirements with more flexibility, potentially having children in shorter or less stable relationships.

This fact should be reflected in the following situations:

1. Older single women may be more likely to enter motherhood shortly after starting a union.
2. Older partnered women may be more likely to end a relationship shortly after having a child.
3. Older women may be more likely to have children without a partner.

2. Data and Methods

- Database: European Union Statistics on Income and Living Conditions (**EUSILC**) – longitudinal aspect.
 - Information about the household composition and relationship between its members for 4 observations.
- We analyse how the situation in the first observation (t1) is connected to the behaviours observed in the three subsequent observations (t2, t3, and t4).
- Pooling different countries and time periods (2004-2023), we observe **variations across time and space** (clustering countries according to fertility characteristics).

2. Data and Methods

1. Among single childless women at t_1 who enter a co-residential union at t_2 or t_3 , likelihood of having a child in t_2 , t_3 or t_4 , by age.
2. Among childless women having a child in a co-residential union in t_1 , t_2 or t_3 , likelihood of ending co-residential unions in t_2 , t_3 or t_4 , by age.
3. Among childless single women in t_1 , t_2 or t_3 , likelihood of having a child outside of a co-residential union in t_2 , t_3 or t_4 , by age.

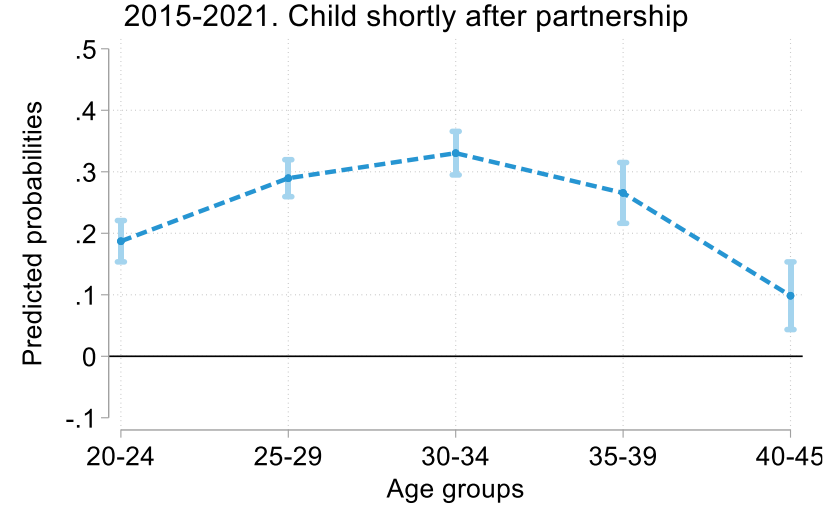

2. Data and Methods

- 1.** Among single childless women at t_1 who enter a co-residential union at t_2 or t_3 , likelihood of having a child in t_2 , t_3 or t_4 , by age.
- 2.** Among childless women having a child in a co-residential union in t_1 , t_2 or t_3 , likelihood of ending co-residential unions in t_2 , t_3 or t_4 , by age.
- 3.** Among childless single women in t_1 , t_2 or t_3 , likelihood of having a child outside of a co-residential union in t_2 , t_3 or t_4 , by age.

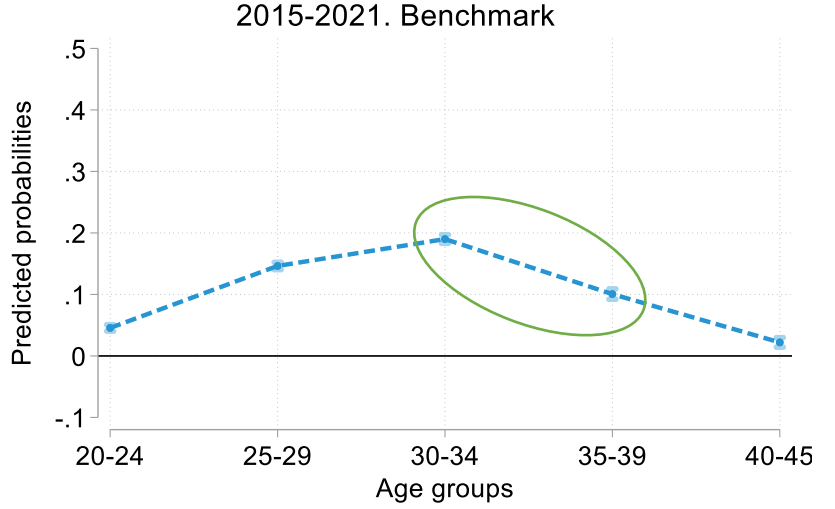

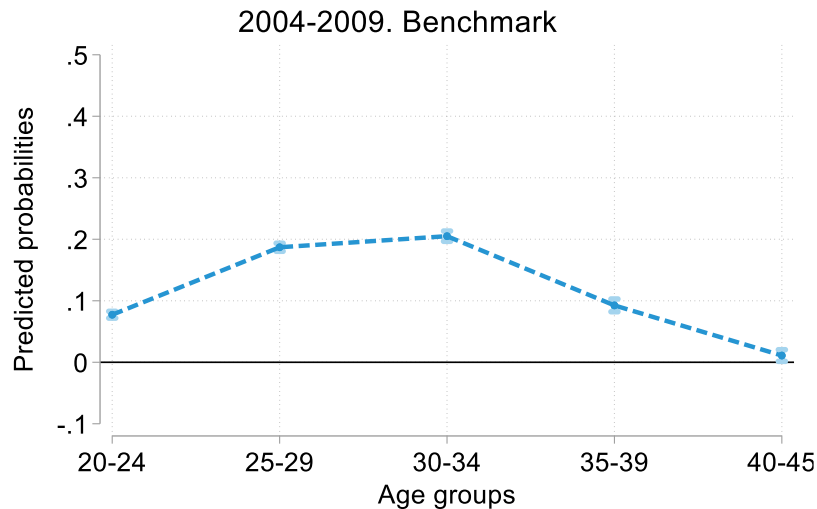

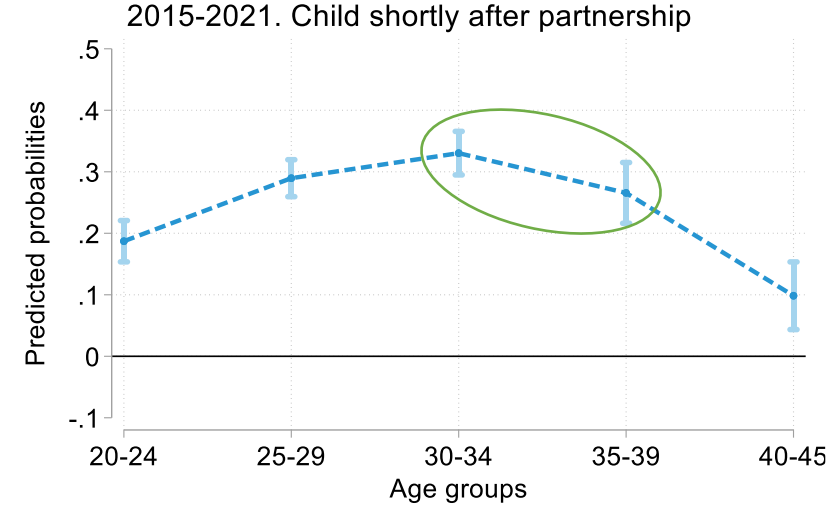

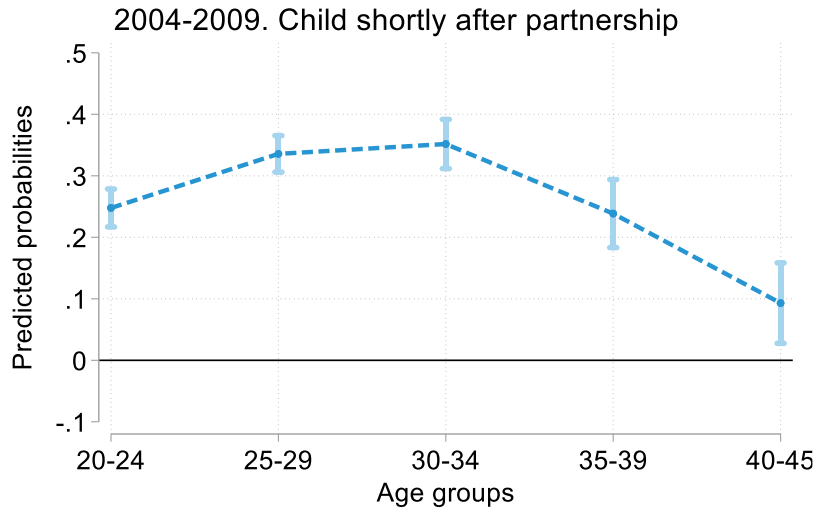

3. Results. Variations across time

Predicted probabilities of having a child during the observation period among women single in t1 who begin a co-residential union during the observation period, by age and period

3. Results. Variations across time

Predicted probabilities of having a child during the observation period among women single in t1 who begin a co-residential union during the observation period, by age and period

4. Conclusions

- We observe an **increased likelihood of older women entering motherhood** after initiating co-residential unions **over time** (1) -> more prevalent as fertility has been postponed.
- Single older women entering a co-residential union **are more likely to transition to motherhood during the observation period in countries with late fertility patterns** compared to those with earlier fertility patterns (1) -> the relationship seems to relate to what is considered late in a country.
- We do **not find a clear trend indicating that older women are more likely to experience union dissolutions** after entering motherhood (2). However, the findings suggest that **older women are more likely to experience single motherhood** (3).

Thank you!
